

Study Registration: NCT02950961

Title

Implementation of Tailored Collaborative Care For Women Veterans (CCWV) (QUE 15-272)

Brief Summary

Implementation of Tailored Collaborative Care for Women Veterans (CCWV) was designed to enhance primary care-mental health integration for women Veterans by tailoring services to women Veterans' and providers' needs and providing an evidence-based intervention, Coordinated Anxiety Learning and Management, to address anxiety and depression in a patient-centered approach. CCWV was implemented in two of the Women's Health Practice-Based Research Network sites, with careful attention to local tailoring and adaptation to enhance the fit of the care model in varied local contexts.

Status: COMPLETED

Phase: NA

Primary Outcomes

1. Change in Utilization of Services (30 Days)

Eligibility Criteria

Inclusion Criteria

Patient Participants:

- * Women VA patients with possible or confirmed anxiety and/or depression and/or PTSD

Provider Participants:

- * VA staff in a primary care and/or mental health clinic
- * Note: gender based inclusion criteria did not apply to provider participants

Exclusion Criteria

Patient Participants:

- * Male gender

Provider Participants:

- * None

Planned Enrollment: 153

Study Arms

- **Arm 1: Mixed Methods Implementation Evaluation** (OTHER): The investigators used mixed methods to evaluate the implementation in two VA Women's Practice Based Research Network (PBRN) sites, describing services and patterns of care utilized by patients prior to seeing a care manager, and then 30, 60, 180, and 365 days post initiation of care with the care manager. Investigators also evaluated facilitators and barriers to implementation of this collaborative care model.

Interventions

- **Collaborative Care for Women Veterans** (BEHAVIORAL): This is a collaborative care model that focuses on

identifying need for depression and/or anxiety care. Patients with possible anxiety and/or depression are referred to a care manager in primary care-mental health integration. The care manager then conducts a thorough assessment, offers the patient a variety of appropriate treatment options, and works with the patient to determine a care plan. One of the key options the investigators offered in this study is the Calm Tools for Living (CALM) intervention, which is focused on anxiety and which is rooted in patient preferences. Patients can choose web-based cognitive behavioral therapy (CBT) and/or pharmacologic treatment. In this study the investigators trained appropriate MH providers in CALM and studied the ways in which the intervention needs to be tailored to women Veterans.
